Satellite Orbit and clock accuracies

Broadcast:

Few metres of accuracy for broadcast orbits and clocks

Transmitted in the satellite navigation message.

Precise:

Few centimetres of accuracy for precise orbits and clocks

Precise clocks for GPS satellites can be found on the International GNSS Service (IGS) server <http://igsceb.jpl.nasa.gov>

IGS Precise orbit and clock products:

RMS accuracy, latency and sampling

Products (delay)	Broadcast (real time)	Ultra-rapid		Rapid (17–41 h)	Final (12–18 d)
		Predicted (real time)	Observed (3–9 h)		
Orbit GPS (sampling)	~100 cm (~2 h)	~5 cm (15 min)	~3 cm (15 min)	~2.5cm (15 min)	~ 2.5 cm (15 min)
Glonass (sampling)					~5 cm (15 min)
Clock GPS (sampling)	~5 ns (daily)	~3 ns (15 min)	~150 ps (15 min)	~75 ps (5 min)	~75 ps (30 s)
Glonass (sampling)					~ TBD (15 min)

<http://igscb.jpl.nasa.gov/components/prods.html>

Computation of satellite coordinates from precise products.

Precise orbits for GPS satellites can be found on the International GNSS Service (IGS) server <http://igscb.jpl.nasa.gov>

Orbits are given by (x,y,z) coordinates with a sampling rate of 15 minutes. The satellite coordinates between epochs can be computed by polynomial interpolation. A 10th-order polynomial is enough for a centimetre level of accuracy with 15 min data.

$$\begin{aligned}
 P_n(x) &= \sum_{i=1}^n y_i \frac{\prod_{j \neq i} (x - x_j)}{\prod_{j \neq i} (x_i - x_j)} \\
 &= y_1 \frac{x - x_2}{x_1 - x_2} \cdots \frac{x - x_n}{x_1 - x_n} + \cdots \\
 &\quad + y_i \frac{x - x_1}{x_i - x_1} \cdots \frac{x - x_{i-1}}{x_i - x_{i-1}} \frac{x - x_{i+1}}{x_i - x_{i+1}} \cdots \frac{x - x_n}{x_i - x_n} + \cdots \\
 &\quad + y_n \frac{x - x_1}{x_n - x_1} \cdots \frac{x - x_{n-1}}{x_n - x_{n-1}}
 \end{aligned}$$

IGS orbit and clock products (for PPP):

Discrepancy between the different centres

Computation of satellite clocks from precise products

Precise clocks for GPS satellites can be found on the International GNSS Service (IGS) server <http://igscb.jpl.nasa.gov>

IGS is providing precise orbits and clock files with a sampling rate of 15 min, as well as precise clock files with a sample rate of 5 min and 30 sec, in SP3 and CLK formats.

Some centres also provide GPS satellite clocks with a 5 sec sampling rate, like the les obtained from the Crustal Dynamics Data Information System (CDDIS) site.

Stable clocks with a sampling rate of 30 sec or higher can be interpolated with a first-order polynomial to a few centimetres of accuracy. Clocks with a lower sampling rate should not be interpolated, because clocks evolve as random walk processes.

Session 3.2, Ex7a: Precise 300s clock interpolation error

Measurements: Code and carrier

For high-accuracy positioning, the carrier phase must be used, besides the code pseudorange.

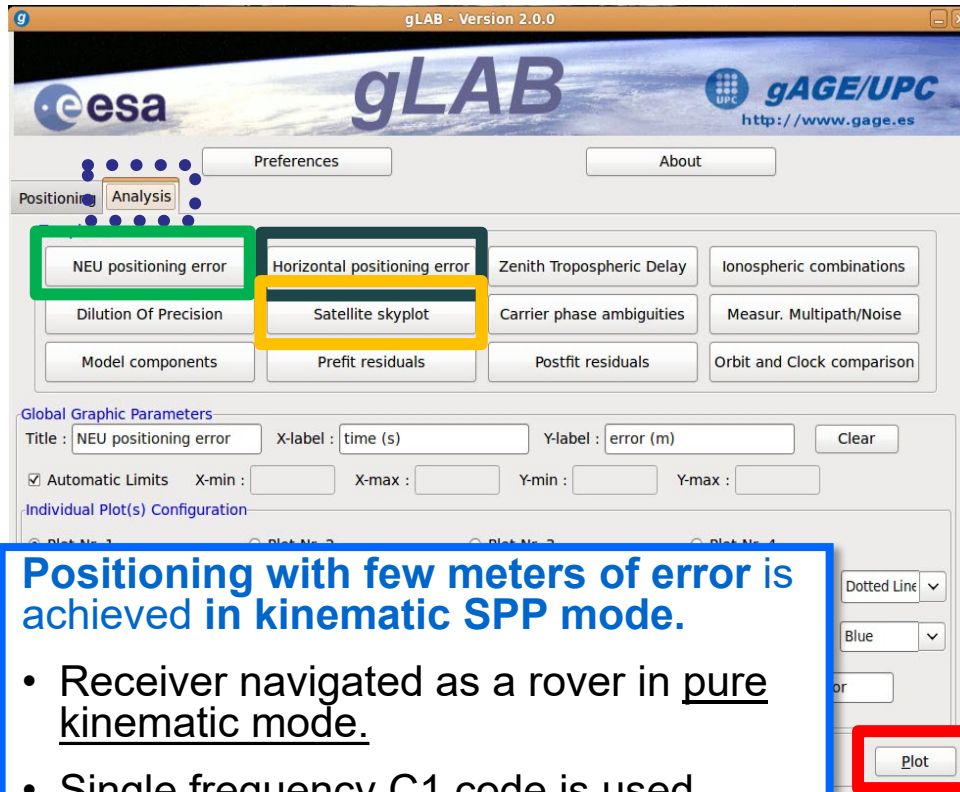

The carrier measurements are very precise, typically at the level of a few millimetres, but contain unknown ambiguities which change every time the receiver locks the signal after a cycle slip.

Nevertheless, such ambiguities can be estimated in the navigation solution, together with the coordinates and other parameters.

Example 1: Standard Point Positioning (SPP)

Plotting Results

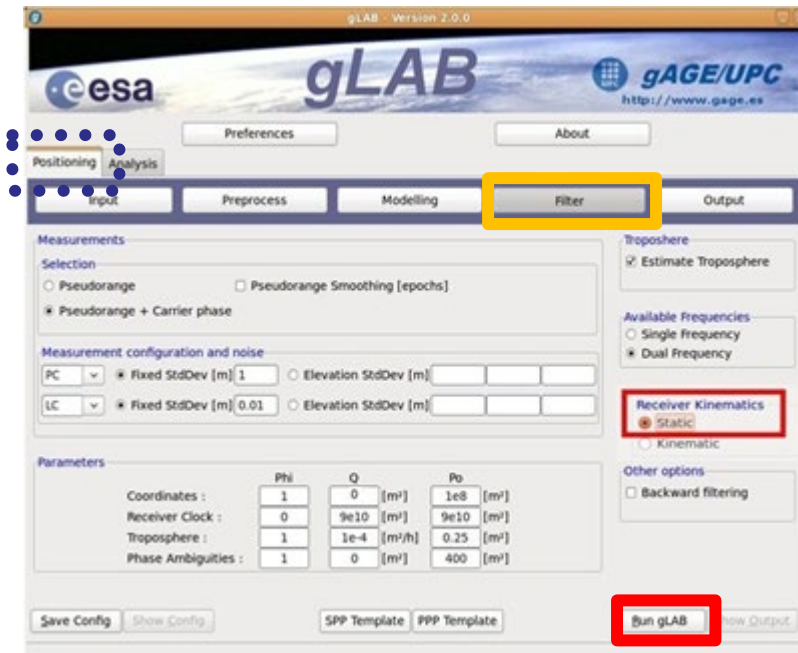

Positioning with few meters of error is achieved in kinematic SPP mode.

- Receiver navigated as a rover in pure kinematic mode.
- Single frequency C1 code is used.
- Broadcast orbits and clocks.

Precise Point Positioning: Static

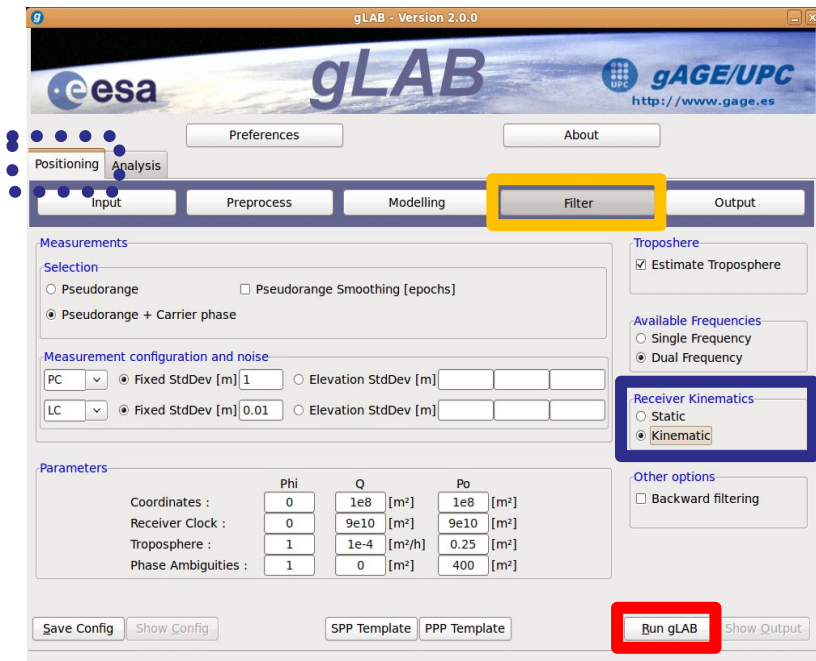

From default configuration of [PPP Template],
Select **Static** in the [Filter] panel. **Run gLAB** and plot results

Receiver positioned as a permanent station (static mode)

Precise Point Positioning: Kinematic

From default configuration of [PPP Template],
Select kinematics in the [Filter] panel. **Run gLAB** and plot results

Receiver navigated as a rover
in a pure kinematic mode.

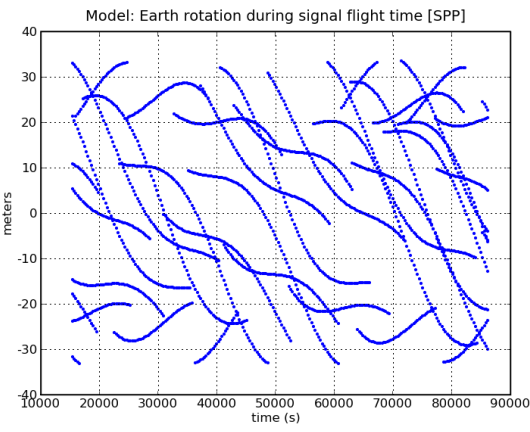

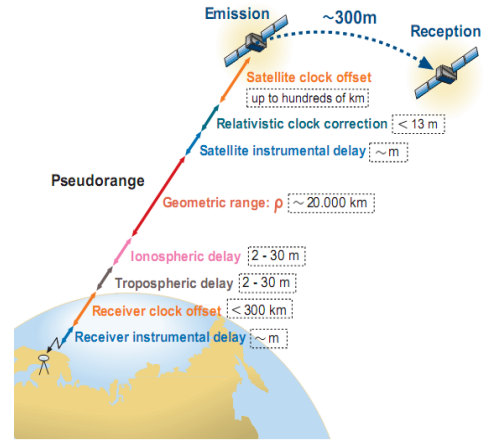

PPP Model components

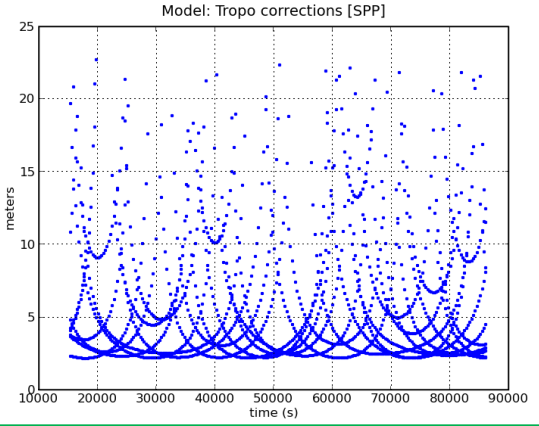

We are going to review first the measurements modelling for the Standard Point Positioning (SPP). A brief summary is given next.

After this summary, we will focus on the additional modelling need for Precise Point Positioning.

Remember that the error component most difficult to model is the ionosphere. But, in the PPP technique the ionosphere error is removed (more than 99.9%) using dual-frequency measurements in the ionosphere-free combination (L_c, P_c). This combination also removes the Differential Code Bias (or TGD).

Satellite coordinates computation at signal emission time

Ionosphere error is removed using dual-frequency measurements

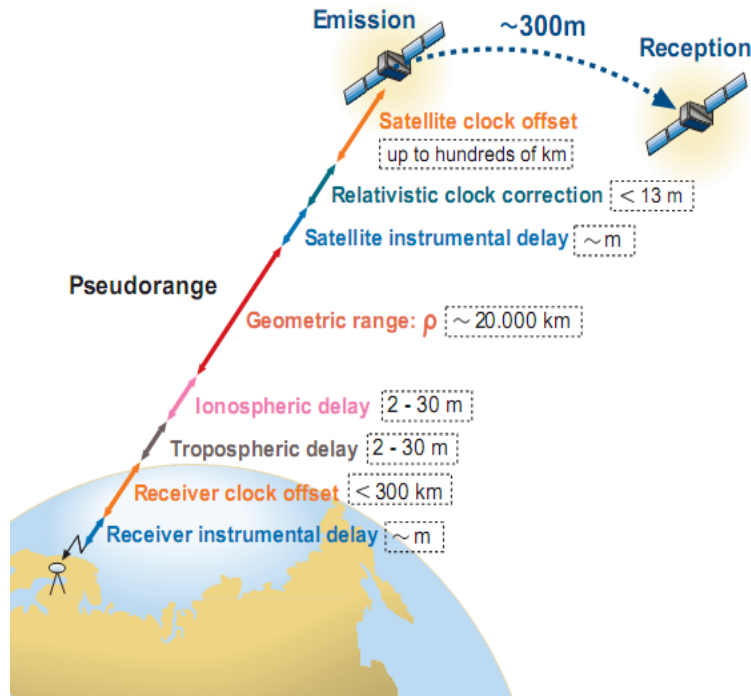

Signal propagation errors on the Atmosphere

TGDs cancel in the ionosphere-free combination

Satellite clocks and Total Group Delay (TGD)

Additional Modelling for PPP

The PPP technique allows centimetre-level of accuracy to be achieved for static positioning and decimetre level, or better, for kinematic navigation.

This high accuracy requires an accurate **modelling “up to the centimetre level or better”**, where all previous model terms must be taken into account (except ionosphere and TGD [*]), **plus some additional terms given next:**

[*] Remember that in the PPP technique the ionosphere error is removed (more than 99.9%) using dual-frequency measurements in the ionosphere-free combination (L_c, P_c). This combination also removes the Differential Code Bias (or TGD).

Additional Modelling for PPP

Satellite Mass Center to Antenna Phase Center

Broadcast orbits are referred to the antenna phase center, but IGS precise orbits are referred to the satellite mass center.

Satellite MC to APC:

The satellite MC to APC eccentricity vector depends on the satellite. The APC values used in the IGS orbits and clocks products are referred to the iono-free combination (LC, PC). They are given in the IGS ANTEX files (e.g., igs05.atx).

Additional Modelling for PPP

Receiver Antenna Phase center (APC)

Receiver APC:

The antenna used for this experiment, has the APC position vertically shifted regarding ARP.

Thence, neglecting this correction, an error on the vertical component occurs, but not in the horizontal one.

Additional Modelling for PPP: APC

Antenna biases and orientation:

- The satellite and receiver **antenna phase centres (APCs)** can be found in the IGS ANTEX files, after GPS week 1400 (Nov. 2006)
- The **carrier phase wind-up** effect due to the satellite's motion must be taken into account.

Additional Modelling for PPP

Wind-up affects only carrier phase. It is due to the electromagnetic nature of circularly polarized waves of GNSS signals.

As the satellite moves along its orbital path, it performs a rotation to keep its solar panels pointing to the Sun direction. This rotation causes a carrier variation, and thence, a range measurement variation.

Wind-Up

Wind-up changes smoothly along continuous carrier phase arcs.

In the position domain, wind-up affects both vertical and horizontal components.

Additional Modelling for PPP: Eclipse condition

High-accuracy GNSS positioning degrades during the GNSS satellites' eclipse seasons.

- Once the satellite goes into shadow, the radiation pressure vanishes. This effect introduces errors in the satellite dynamics due to the difficulty of properly modelling the solar radiation pressure.
- On the other hand, the satellite's solar sensors lose sight of the Sun and the attitude control (trying to keep the panels facing the Sun).

As a consequence, the orbit during shadow and eclipse periods may be considerably degraded and the removal of satellites under such conditions can improve the high-accuracy positioning results.

- The **ionospheric refraction and TGDs** are **removed** using the ionosphere-free combination of code and carrier measurements (PC, LC).
- The **tropospheric refraction can be modelled by Dry and Wet components** (and different mappings are usually used for both components, e.g. mapping of Niell).

- A **residual tropospheric delay is estimated** (as wet ZTD delay) in the Kalman filter, together with the coordinates, clock and carrier phase ambiguities.

Earth deformation effects:

- **Solid tides** must be modelled by equations
- **Ocean loading and pole tides** are second-order effects and can be neglected for PPP accuracies at the centimetre level

Solid Tides concern the movement of Earth's crust (and thus the variation in the receiver's location coordinates) due to gravitational attractive forces produced by external bodies, mainly the Sun and Moon. Solid tides produce vertical and horizontal displacements that can be expressed by the spherical harmonics expansion (m, n) , characterised by the Love and Shida numbers h_{mn} and l_{mn} .

Additional Modelling for PPP

Solid Tides

It comprises the Earth's crust movement (and thence receiver coordinates variations) due to the gravitational attraction forces produced by external bodies, mainly the Sun and the Moon.

Solid Tides:

These effects do not affect the GNSS signals, but if they were not considered, the station coordinates would oscillate with relation to a mean value.

They produce vertical (mainly) and horizontal displacements.

3. Code and carrier measurements and modelling errors
4. **Linear observation model for PPP**
5. Parameter estimation: Floating Ambiguities
6. Carrier Ambiguity fixing concept: DD and undifferenced
7. Accelerating Filter convergence with accurate ionosphere

Linear observation model for PPP

It is based code and carrier measurements in the ionosphere-free combination (P_c , L_c), which are modelled as follows:

$$P_{Crec}^{sat} = \rho_{rec}^{sat} + c \cdot (dt_{rec} - dt^{sat}) + Trop_{rec}^{sat} + \mathcal{M}_{Pc} + \varepsilon_{Pc}$$

$$L_{Crec}^{sat} = \rho_{rec}^{sat} + c \cdot (dt_{rec} - dt^{sat}) + Trop_{rec}^{sat} + \lambda_N \omega_{rec}^{sat} + B_{Crec}^{sat} + \mathcal{M}_{Lc} + \varepsilon_{Lc}$$

where

$$P_C = \frac{f_1^2 P_1 - f_2^2 P_2}{f_1^2 - f_2^2}; \quad L_C = \frac{f_1^2 L_1 - f_2^2 L_2}{f_1^2 - f_2^2}$$

Ionosphere is removed

$$B_C = \lambda_N \left(B_1 + \frac{\lambda_W}{\lambda_2} B_W \right)$$

$$B_W = B_1 - B_2$$

$$\lambda_N = 10.7 \text{ cm}, \quad \lambda_W = 86.2 \text{ cm}$$

Remark, ρ is referred to the Antenna Phase Centres (APC) of satellite and receiver antennas in the ionosphere free combination.

Linear model: For each satellite in view

$$P_{C \text{ rec}}^{\text{sat}} = \rho_{\text{rec}}^{\text{sat}} + c \cdot (dt_{\text{rec}} - dt^{\text{sat}}) + Trop + \varepsilon$$

Linearising ρ around an 'a priori' receiver position $(x_{\text{rec},0}, y_{\text{rec},0}, z_{\text{rec},0})$

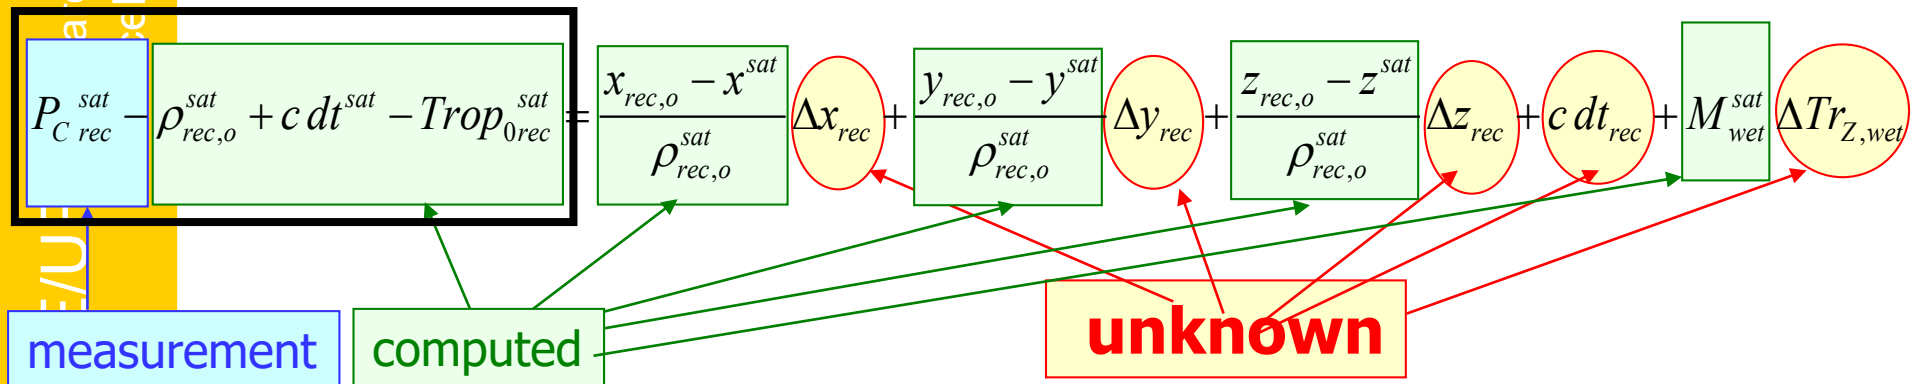

$$= \rho_{\text{rec},0}^{\text{sat}} + \frac{x_{\text{rec},0} - x^{\text{sat}}}{\rho_{\text{rec},0}^{\text{sat}}} \Delta x_{\text{rec}} + \frac{y_{\text{rec},0} - y^{\text{sat}}}{\rho_{\text{rec},0}^{\text{sat}}} \Delta y_{\text{rec}} + \frac{z_{\text{rec},0} - z^{\text{sat}}}{\rho_{\text{rec},0}^{\text{sat}}} \Delta z_{\text{rec}} + c(dt_{\text{rec}} - dt^{\text{sat}}) + Trop$$

where:

$$\Delta x_{\text{rec}} = x_{\text{rec}} - x_{\text{rec},0} \quad ; \quad \Delta y_{\text{rec}} = y_{\text{rec}} - y_{\text{rec},0} \quad ; \quad \Delta z_{\text{rec}} = z_{\text{rec}} - z_{\text{rec},0}$$

and taking: $Trop_{\text{rec}}^{\text{sat}} = Trop_{0 \text{ rec}}^{\text{sat}} + M_{\text{wet}, \text{rec}}^{\text{sat}} \Delta Tr_{Z, \text{wet}}$

Prefit-residuals (Prefit)

The same for carrier, but adding the ambiguity as an unknown

Remark

$$P_C^{sat} = \rho_{rec}^{sat} + c \cdot (dt_{rec} - dt^{sat}) + Trop + \varepsilon$$

Linearising ρ around an 'a priori' receiver position $(x_{rec,0}, y_{rec,0}, z_{rec,0})$

$$= \rho_{rec,0}^{sat} + \frac{x_{rec,0} - x^{sat}}{\rho_{rec,0}^{sat}} \Delta x_{rec} + \frac{y_{rec,0} - y^{sat}}{\rho_{rec,0}^{sat}} \Delta y_{rec} + \frac{z_{rec,0} - z^{sat}}{\rho_{rec,0}^{sat}} \Delta z_{rec} + c(dt_{rec} - dt^{sat}) + Trop$$

Of course, receiver coordinates $(x_{rec}, y_{rec}, z_{rec})$ are not known (they are the target of this problem). But, we can always assume that an "approximate position $(x_{0,rec}, y_{0,rec}, z_{0,rec})$ is known".

Thence, the navigation problem will consist on:

- 1.- To start from an approximate value for receiver position $(x_{0,rec}, y_{0,rec}, z_{0,rec})$ e.g. the Earth's centre) to linearise the equations
- 2.- With the pseudorange measurements and the navigation equations, compute the correction $(\Delta x_{rec}, \Delta y_{rec}, \Delta z_{rec})$ to have improved estimates:

$$(x_{rec}, y_{rec}, z_{rec}) = (x_{0,rec}, y_{0,rec}, z_{0,rec}) + (\Delta x_{rec}, \Delta y_{rec}, \Delta z_{rec})$$
- 3.- Linearise the equations again, about the new improved estimates, and iterate until the change in the solution estimates is small enough.

Linear model: For each satellite in view

$$P_{C\ rec}^{sat} = \rho_{rec}^{sat} + c \cdot (dt_{rec} - dt^{sat}) + Trop + \varepsilon$$

Linearising ρ around an 'a priori' receiver position $(x_{rec,0}, y_{rec,0}, z_{rec,0})$

$$= \rho_{rec,0}^{sat} + \frac{x_{rec,0} - x^{sat}}{\rho_{rec,0}^{sat}} \Delta x_{rec} + \frac{y_{rec,0} - y^{sat}}{\rho_{rec,0}^{sat}} \Delta y_{rec} + \frac{z_{rec,0} - z^{sat}}{\rho_{rec,0}^{sat}} \Delta z_{rec} + c(dt_{rec} - dt^{sat}) + Trop$$

where:

$$\Delta x_{rec} = x_{rec} - x_{rec,0} \quad ; \quad \Delta y_{rec} = y_{rec} - y_{rec,0} \quad ; \quad \Delta z_{rec} = z_{rec} - z_{rec,0}$$

and taking: $Trop_{rec}^{sat} = Trop_{0\ rec}^{sat} + M_{wet,rec}^{sat} \Delta Tr_{Z,wet}$

Prefit-residuals (Prefit)

The same for carrier, but adding the ambiguity as an unknown

Linear model: For each satellite in view

$$P_{C\ rec}^{sat} = \rho_{rec}^{sat} + c \cdot (dt_{rec} - dt^{sat}) + Trop + \varepsilon$$

Linearising ρ around an 'a priori' receiver position $(x_{rec,0}, y_{rec,0}, z_{rec,0})$

$$= \rho_{rec,0}^{sat} + \frac{x_{rec,0} - x^{sat}}{\rho_{rec,0}^{sat}} \Delta x_{rec} + \frac{y_{rec,0} - y^{sat}}{\rho_{rec,0}^{sat}} \Delta y_{rec} + \frac{z_{rec,0} - z^{sat}}{\rho_{rec,0}^{sat}} \Delta z_{rec} + c(dt_{rec} - dt^{sat}) + Trop$$

where:

$$\Delta x_{rec} = x_{rec} - x_{rec,0} \quad ; \quad \Delta y_{rec} = y_{rec} - y_{rec,0} \quad ; \quad \Delta z_{rec} = z_{rec} - z_{rec,0}$$

and taking: $Trop_{rec}^{sat} = Trop_{0\ rec}^{sat} + M_{wet,rec}^{sat} \Delta Tr_{Z,wet}$

Prefit-residuals (Prefit)

$$P_{C\ rec}^{sat} - \rho_{rec,0}^{sat} + c dt^{sat} - Trop_{0\ rec}^{sat} = \frac{x_{rec,0} - x^{sat}}{\rho_{rec,0}^{sat}} \Delta x_{rec} + \frac{y_{rec,0} - y^{sat}}{\rho_{rec,0}^{sat}} \Delta y_{rec} + \frac{z_{rec,0} - z^{sat}}{\rho_{rec,0}^{sat}} \Delta z_{rec} + c dt_{rec} + M_{wet}^{sat} \Delta Tr_{Z,wet}$$

$$L_{C\ rec}^{sat} - \rho_{rec,0}^{sat} + c dt^{sat} - Trop_{0\ rec}^{sat} - \lambda_N \omega^{sat} = \frac{x_{rec,0} - x^{sat}}{\rho_{rec,0}^{sat}} \Delta x_{rec} + \frac{y_{rec,0} - y^{sat}}{\rho_{rec,0}^{sat}} \Delta y_{rec} + \frac{z_{rec,0} - z^{sat}}{\rho_{rec,0}^{sat}} \Delta z_{rec} + c dt_{rec} + M_{wet}^{sat} \Delta Tr_{Z,wet} + B_C^{sat}$$

Following the same procedure as with the code based positioning (SPP), the linear observation model $\mathbf{y} = \mathbf{G} \mathbf{x}$ for the code and carrier measurements can be written as follows:

$$\mathbf{y} = \mathbf{G} \mathbf{x}$$

$$\begin{bmatrix} \text{Prefit}(P_C)^1 \\ \text{Prefit}(L_C)^1 \\ \dots \\ \text{Prefit}(P_C)^n \\ \text{Prefit}(L_C)^n \end{bmatrix} = \begin{bmatrix} \frac{x_{o,rec} - x^1}{\rho_{0,rec}^1} & \frac{y_{o,rec} - y^1}{\rho_{0,rec}^1} & \frac{z_{o,rec} - z^1}{\rho_{0,rec}^1} & 1 & M_{wet}^1 & 0 & \dots & \dots & 0 \\ \frac{x_{o,rec} - x^1}{\rho_{0,rec}^1} & \frac{y_{o,rec} - y^1}{\rho_{0,rec}^1} & \frac{z_{o,rec} - z^1}{\rho_{0,rec}^1} & 1 & M_{wet}^1 & 1 & \dots & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ \frac{x_{o,rec} - x^n}{\rho_{0,rec}^n} & \frac{y_{o,rec} - y^n}{\rho_{0,rec}^n} & \frac{z_{o,rec} - z^n}{\rho_{0,rec}^n} & 1 & M_{wet}^n & 0 & \dots & \dots & 0 \\ \frac{x_{o,rec} - x^n}{\rho_{0,rec}^n} & \frac{y_{o,rec} - y^n}{\rho_{0,rec}^n} & \frac{z_{o,rec} - z^n}{\rho_{0,rec}^n} & 1 & M_{wet}^n & 0 & \dots & \dots & 1 \end{bmatrix} \begin{bmatrix} \Delta x_{rec} \\ \Delta y_{rec} \\ \Delta z_{rec} \\ cdt_{rec} \\ \Delta Tr_{Z,wet} \\ B_C^1 \\ \dots \\ B_C^n \end{bmatrix}$$

$$\text{Prefit}(P_C)^k = P_C^k - \rho_0^k + cdt^k - Trop_0^k$$

$$\text{Prefit}(L_C)^k = L_C^k - \rho_0^k + cdt^k - Trop_0^k - \lambda_N \omega^k$$

Carrier ambiguities

Parameter estimation PPP: Floating Ambiguities

The linear observation model $\mathbf{y} = \mathbf{G} \mathbf{x}$ can be solved using the **Kalman filter**. The next stochastic model can be used

- **Carrier phase ambiguities** (B_C) are taken as 'constant' along continuous phase arcs, and as 'white noise' when a cycle slip happens ($\sigma = 10^4 m$ can be taken, for instance) → **FLOATED AMB.**
- **Wet tropospheric delay** ($Tr_{z,wet}$) is taken as a random walk process (with $d\sigma^2/dt = 1 cm^2/h$, for instance).
- **Receiver clock** (cdt) is taken as a white-noise process
(with $\sigma = 3 \cdot 10^5 m$, i.e. $1 ms$ for instance).
- **Receiver coordinates** ($\Delta x, \Delta y, \Delta z$)
 - For **static positioning** the coordinates are taken as constants.
 - For **kinematic positioning** the coordinates are taken as white noise or a random walk process.

Comment: Floating Ambiguities

This solution procedure is called **floating ambiguities**. 'Floating' in the sense that the ambiguities are estimated by the filter 'as real numbers'.

The bias estimations \hat{B}_C will converge to a solution after a transition time that depends on the observation geometry, model quality and data noise.

In general, one must expect errors at the decimetre level, or better, in pure kinematic positioning (after the best part of one hour) and at the centimetre level in static PPP over 24h data.

See exercises in the laboratory session (Tutorial 1).

Carrier Ambiguity Fixing concept

In the previous formulation, the ambiguities have been estimated as real numbers in the Kalman filter, without exploiting its integer nature.

That is, the ambiguities in L_1 , L_2 or L_W signals are an integer number (N) of its associated wavelength (λ) plus a fractional part associated to the satellite and to the receiver.

$$B_{1,rec}^{sat} = \lambda_1 N_{1,rec}^{sat} + b_{1,rec} + b_1^{sat}$$

$$B_{2,rec}^{sat} = \lambda_2 N_{2,rec}^{sat} + b_{2,rec} + b_2^{sat}$$

$$N_W = N_1 - N_2$$

$$B_C = \lambda_N \left(N_1 + \frac{\lambda_w}{\lambda_2} N_W \right) + b_{C,rec} + b_C^{sat}$$

B_C is not an integer number of λ_N but can be related with the integers N_1 , N_W

The Ambiguity Fixing techniques take benefit of this INTEGER NATURE of N_1 , N_2 ambiguities to properly fix them, reducing convergence time, and thence, achieving high accuracy quickly.

Carrier Ambiguity Fixing concept

Two different approaches can be considered:

- **Double differenced Ambiguity Fixing (e.g. RTK):**

This is the classical approach which relies in the fact that the fractional part of carrier ambiguities cancels when forming the double differences between receivers and satellites:

→ That is, given: $B_{rec}^{sat} = \lambda N_{rec}^{sat} + b_{rec} + b^{sat}$

The double differences, regarding a reference receiver and satellite, yield:

$$\Delta\nabla B_{rec}^{sat} = B_{rec}^{sat} - B_{rec,R}^{sat} - (B_{rec}^{sat,R} - B_{rec,R}^{sat,R}) = \lambda \Delta\nabla N_{rec}^{sat}$$

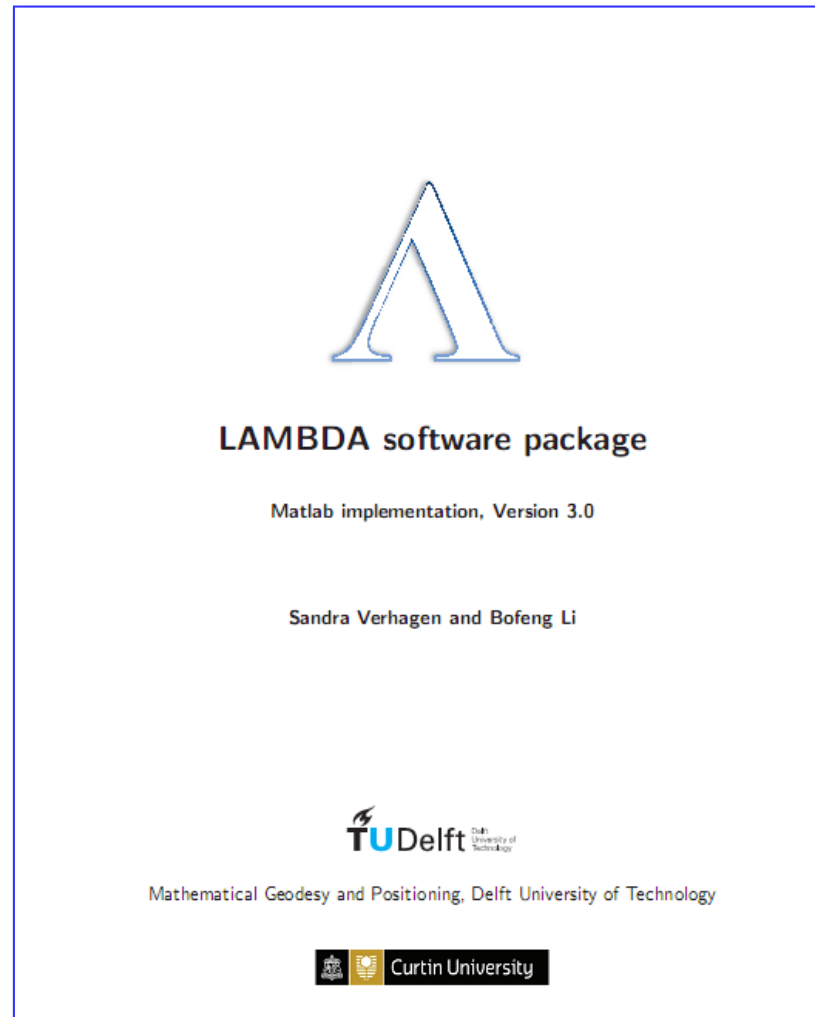

where the satellite and receiver ambiguity terms (b_{rec} , b^{sat}) cancel out.

- **Absolute (or undifferenced) ambiguity fixing (e.g. PPP AR):**

Example of Ambiguity Fixing by rounding

The LAMBDA METHOD

Carrier Ambiguity Fixing concept

Two different approaches can be considered:

- **Double differenced Ambiguity Fixing (e.g. RTK):**

This is the classical approach which relies in the fact that the fractional part of carrier ambiguities cancels when forming the double differences between receivers and satellites:

→ That is, given: $B_{rec}^{sat} = \lambda N_{rec}^{sat} + b_{rec} + b^{sat}$

The double differences, regarding a reference receiver and satellite, yield:

$$\Delta \nabla B_{rec}^{sat} = B_{rec}^{sat} - B_{rec,R}^{sat} - (B_{rec}^{sat,R} - B_{rec,R}^{sat,R}) = \lambda \Delta \nabla N_{rec}^{sat}$$

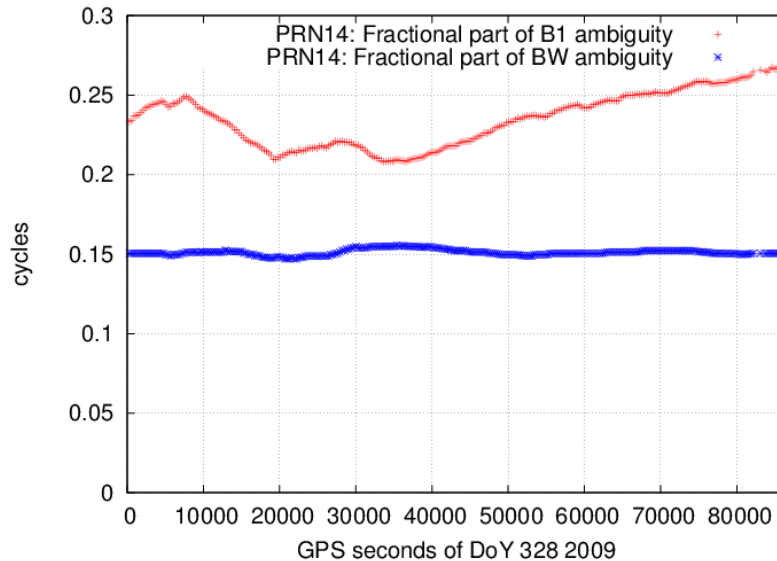

Absolute (or undifferenced) ambiguity fixing (e.g. PPP AR):

This is a new approach, where the fractional part of the ambiguities are estimated from a global network of permanent stations and provided to the users. Thus, the user can remove this fractional part and fix the remaining ambiguity as an integer number.

$$B_{rec}^{sat} = \lambda N_{rec}^{sat} + b_{rec} + b^{sat}$$

Absolute (or undifferenced) ambiguity fixing

Nevertheless, these **carrier hardware biases (or fractional part of carrier ambiguities)** can be estimated together with the orbits, clocks, ionosphere and DCBs from measurements of a worldwide reference stations network.

These carrier hardware biases are **slow varying parameters** and can be broadcast to the user, together with the other differential corrections (orbits, clocks, ionosphere...) from a reference station network.

Then, the user can remove them and estimate the remaining ambiguities as integer numbers.

This can allow world-wide PPP users to perform ambiguity fixing, without baseline length limitation, improving accuracy and reducing convergence time.

Note: These carrier hardware biases are canceled in RTK when forming Double-Differences of measurements between pairs of satellites and receivers.

June 2013

The main weakness of PPP is the large convergence time, which depend on satellites geometry, quality of data (code noise, cycle-slips...).
There is a sudden improvement when fixing carrier ambiguities, but still several tens of minutes are needed to achieve centimeter level of accuracy.

- **How the ionosphere helps the filter convergence in Fast-PPP?**

→ In the classical PPP, the navigation filter convergence is driven by the convergence of the floated iono-free ambiguity (B_C), which, at the beginning, depends on the code noise.

- 1) There is a constraint between the wide-lane ambiguity (B_w), the iono-free ambiguity (B_C) and the ionospheric refraction ($STEC$) and DCB.

$$B_C = B_W - 1.98 (L_1 - L_2 - STEC - DCB)$$

- 2) The wide-lane ambiguity (B_w) is estimated/fixed **quickly** (~5 minutes with 2-freq and in single epoch with 3-freq. signals).
- 3) The ionosphere ($STEC$) is the bridge (through the mentioned constraint) to transfer the quick accuracy achieved in the wide-lane ambiguity (B_w) computed value to the iono-free ambiguity (B_C) estimation, accelerating in this way the filter convergence.

→ Thence, in Fast-PPP the convergence time is strongly reduced thanks to the quick wide-lane ambiguity fixing and the accurate ionospheric corrections. It allows to achieve High Accuracy quickly (~5 minutes with 2-freq & single epoch with 3-freq).

The ionosphere will help provided that its quality (noise/error) is better than the code

300 seconds smoothing

Comparison of measurement noise of LC and PC: GUSN, PRN14

Measurement noise of LC: GUSN, PRN14

- **Code** measurements are unambiguous but noisy (meter level noise).
- **Carrier** measurements are precise (few millimetres of noise) but ambiguous (the unknown ambiguities can reach thousands of km).
- **Carrier phase ambiguities are estimated in the navigation filter** along with the other parameters (coordinates, clock offsets, etc.). If these ambiguities were fixed, measurements accurate to the level of few millimetres would be available for positioning. However, some time is needed to decorrelate such ambiguities from the other parameters in the filter, and the estimated values are not fully unbiased.

Convergence: DoYs 169-200 of 2014

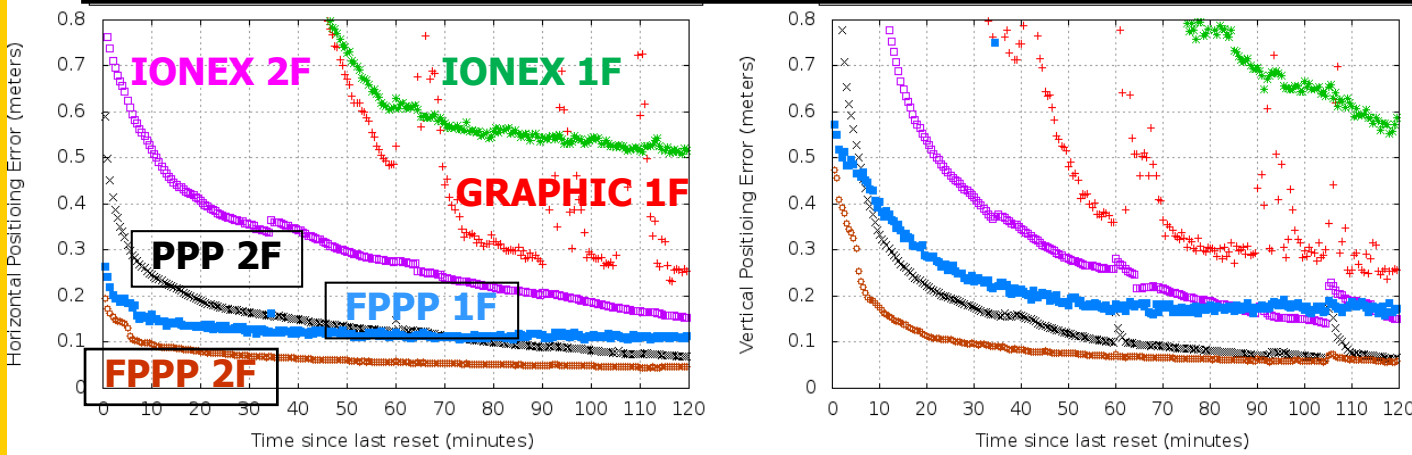

6 Positioning modes per rover, resets every 2h:

- a) Reference Iono-Free sol
- b) Iono Sol: IONEX (IGS-GIM):
- c) Iono Sol. Fast-PPP IONO:
